CUSTOMER SERVICE BULLETIN

Safe Storage of Rubber Products

Rubber products in storage can be adversely affected by the following: temperature, humidity, ozone, sunlight, oils, solvents, corrosive liquids and fumes, insects and 21° C) with a maximum limit of 100° F (38° C). If stored below 32° F (0° C), some products may become stiff and should be warmed before being placed in service. Rubber products should not be stored near source of heat, such radiators and base heaters.

Rubber products should not be stored under conditions of high or low humidity.

To protect against the adverse effects of ozone, rubber products should not be stored near electrical equipment that may generate ozone and should not be stored for any lengthy period in geographical areas of known high ozone concentrations. Exposure to direct and reflected sunlight should also be avoided.

Since certain rodents and insects thrive on rubber products, adequate protection should be provided against them.

Rubber should be stored free from super imposed tensions and compressive stresses or other cause of deformations. Where products are packed in a strain-free condition, they should be stored in their original packaging.
